# Robot motion control

- need to "actually" realize a desired robot motion task ...
  - regulation of pose/configuration (constant reference)
  - trajectory following/tracking (time-varying reference)
- ... despite the presence of
  - external disturbances and/or unmodeled dynamic effects
  - initial errors (or arising later due to disturbances) w.r.t. desired task
  - discrete-time implementation, uncertain robot parameters, ...
- we use a general control scheme based on
  - feedback (from robot state measures, to impose asymptotic stability)
  - feedforward (nominal commands generated in the planning phase)
- the error driving the feedback part of the control law can be defined either in Cartesian or in joint space
  - control action always occurs at the joint level (where actuators drive the robot), but performance has to be evaluated at the task level

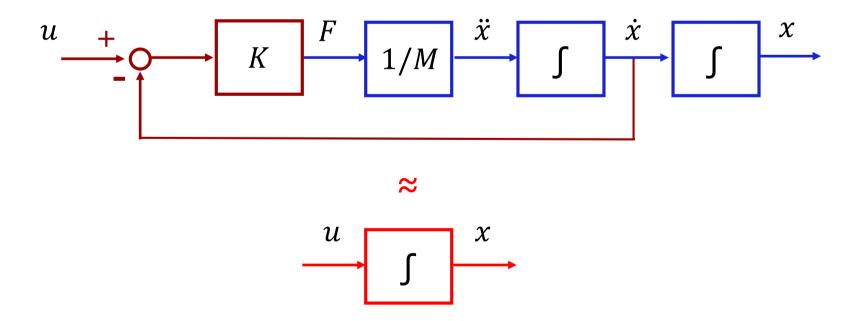

- a robot is an electro-mechanical system driven by actuating torques produced by the motors
- it is possible, however, to consider a kinematic command (most often, a velocity) as control input to the system...
- ...thanks to the presence of low-level feedback control at the robot joints that allows imposing commanded reference velocities (at least, in the "ideal case")
- these feedback loops are present in industrial robots within a "closed" control architecture, where users can only specify reference commands of the kinematic type
- in this way, performance can be very satisfactory, provided the desired motion is not too fast and/or does not require large accelerations

### An introductory example

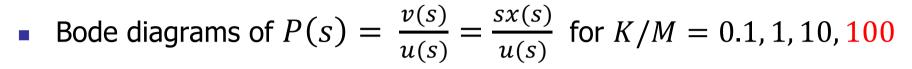

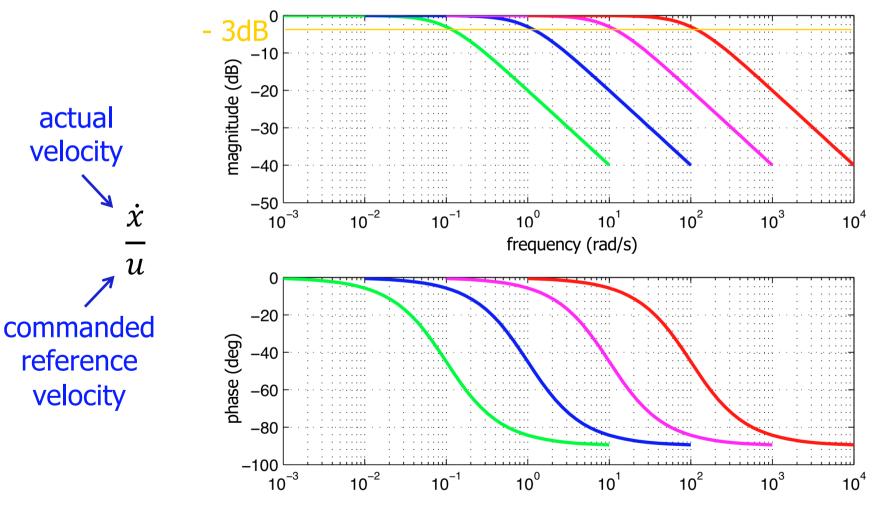

- a mass *M* in linear motion:  $M\ddot{x} = F$
- low-level feedback:  $F = K(u \dot{x})$ , with u = reference velocity
- equivalent scheme for  $K \to \infty$ :  $\dot{x} \approx u$
- in practice, valid in a limited frequency "bandwidth"  $\omega \leq K/M$

#### Frequency response of the closed-loop system

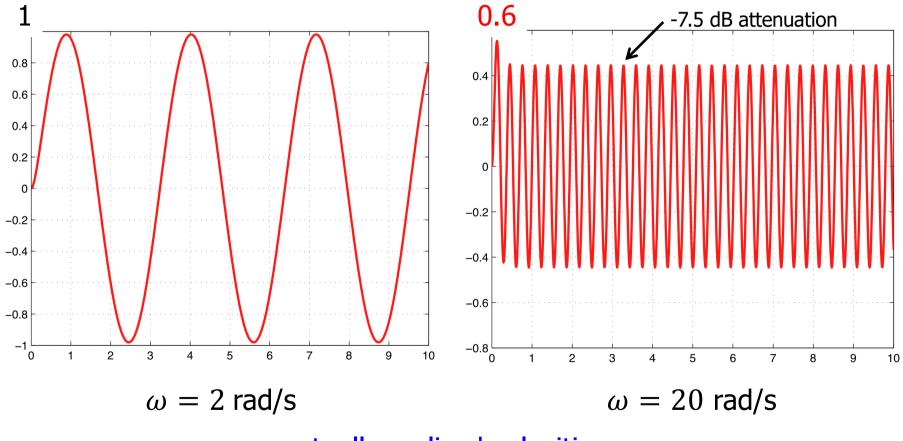

#### Time response

• setting K/M = 10 (bandwidth), we show two possible time responses to unit sinusoidal velocity reference commands at different  $\omega$ 

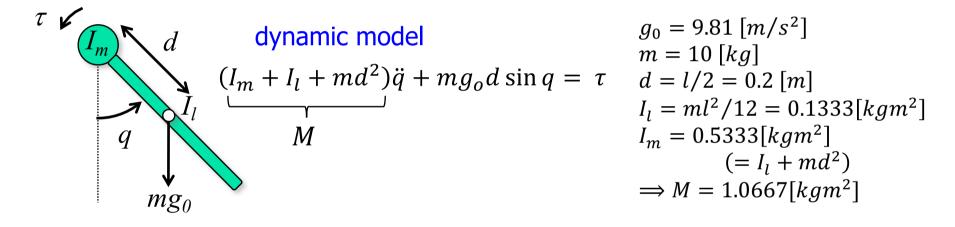

actually realized velocities

# A more detailed example

including nonlinear dynamics

single link (a thin rod) of mass m, center of mass at d from joint axis, inertia M (motor + link) at the joint, rotating in a vertical plane (the gravity torque at the joint is configuration dependent)

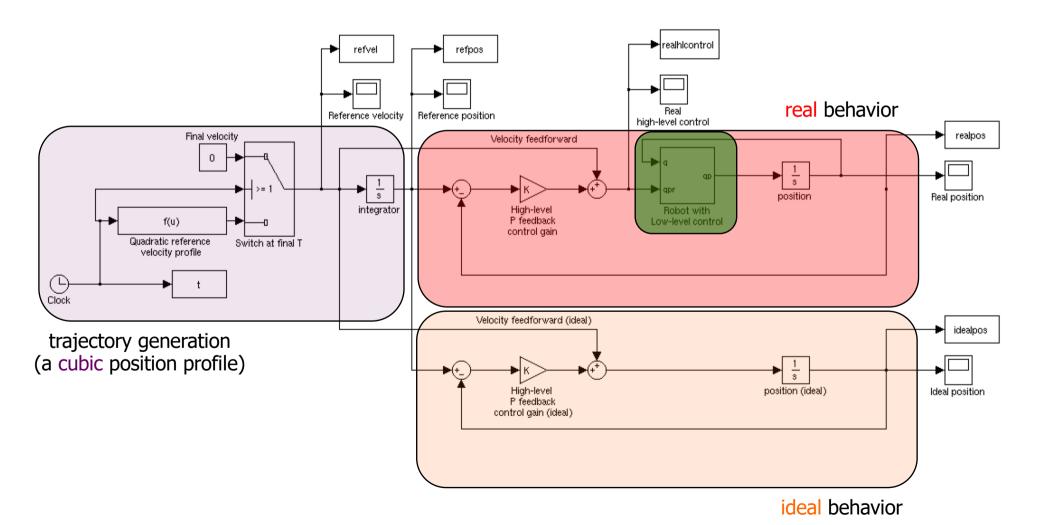

- fast low-level feedback control loop based on a PI action on the velocity error + an approximate acceleration feedforward
- kinematic control loop based on a P feedback action on the position error + feedforward of the velocity reference at the joint level
- evaluation of tracking performance for rest-to-rest motion tasks with "increasing dynamics" = higher accelerations

# A more detailed example

#### differences between the ideal and real case

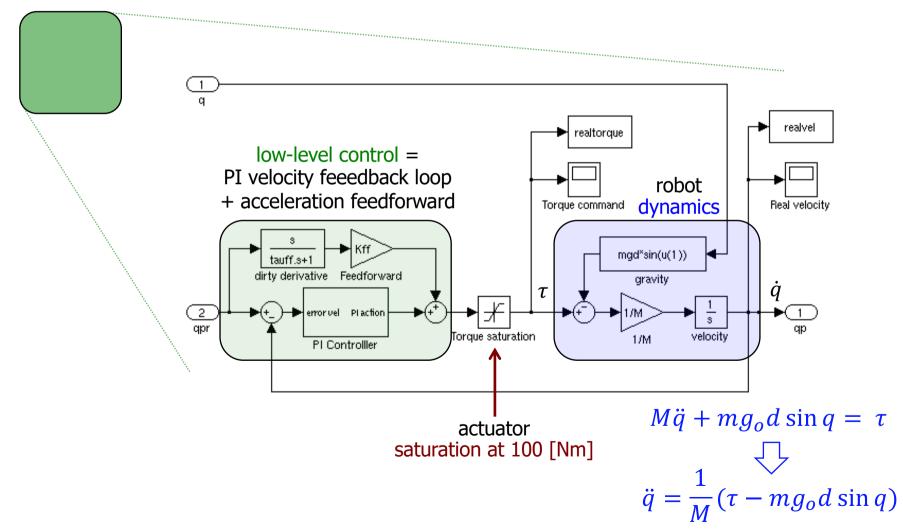

#### Simulink scheme

# A more detailed example

#### robot with low-level control

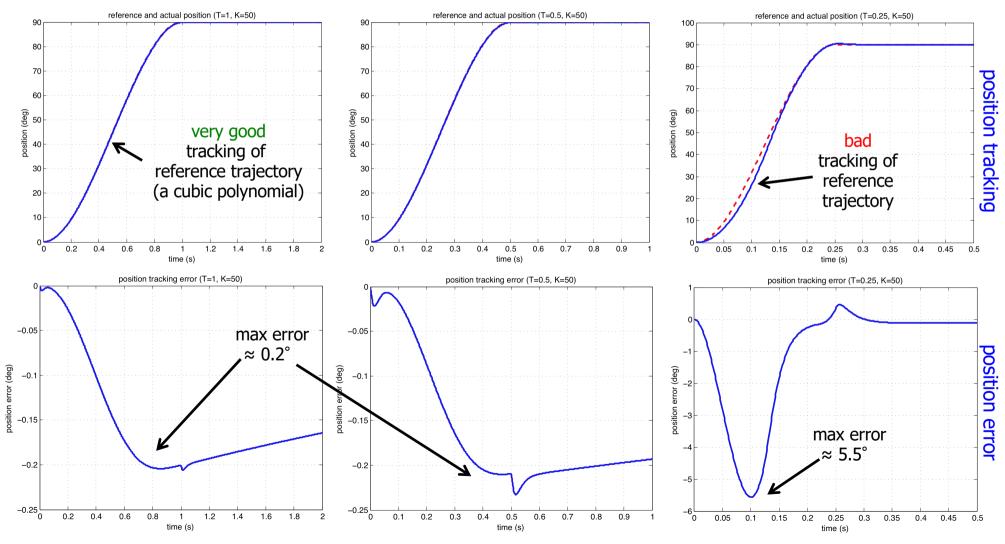

## Simulation results

#### rest-to-rest motion from downward to horizontal position

■ in *T* = 0.5 s

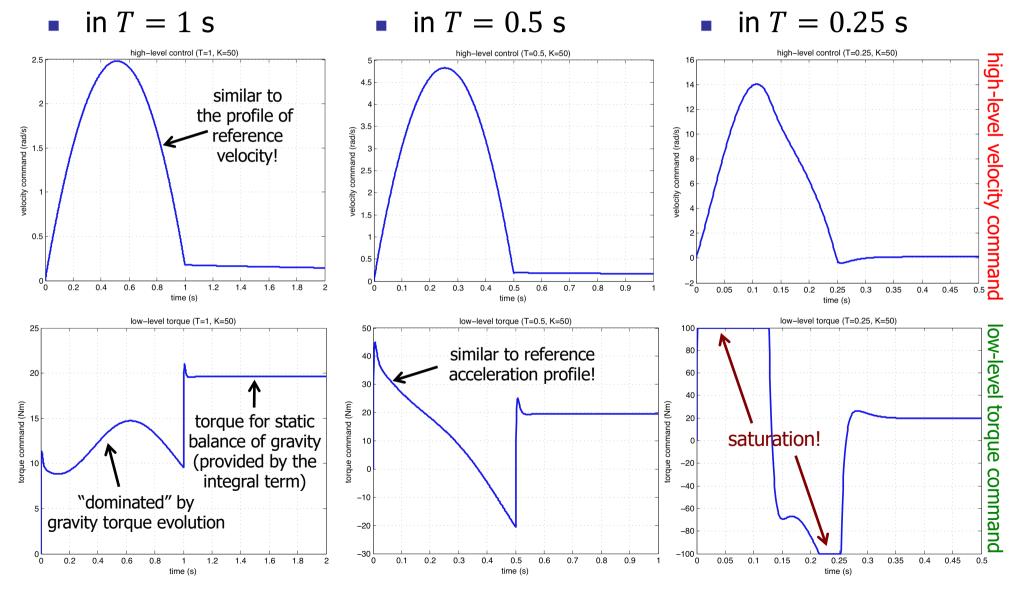

■ in *T* = 0,25 s

# Simulation results

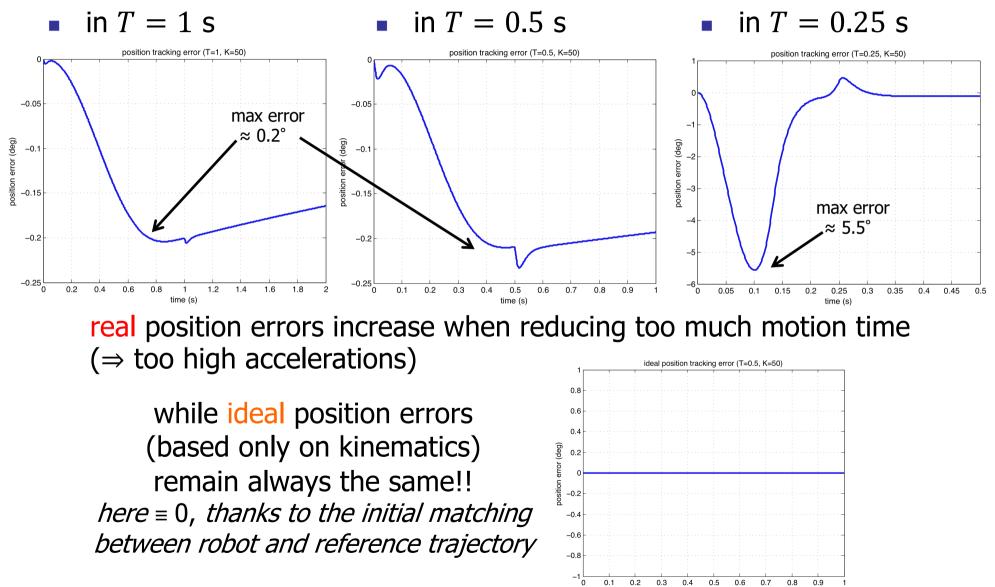

#### rest-to-rest motion from downward to horizontal position

## Simulation results

#### rest-to-rest motion from downward to horizontal position

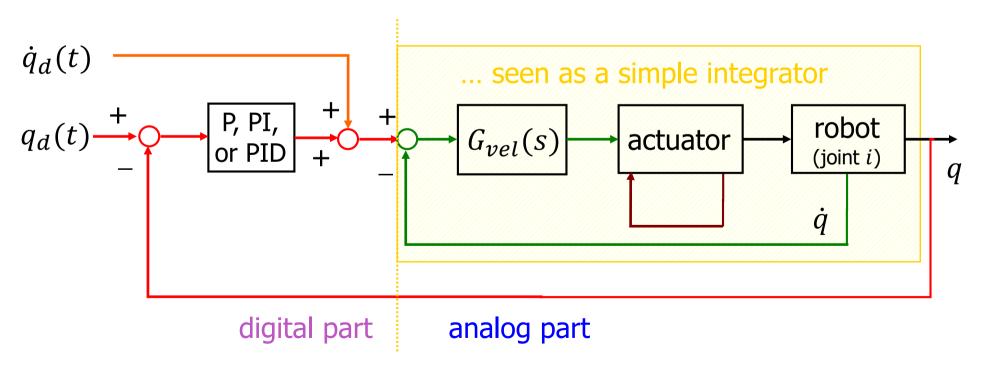

time (s)

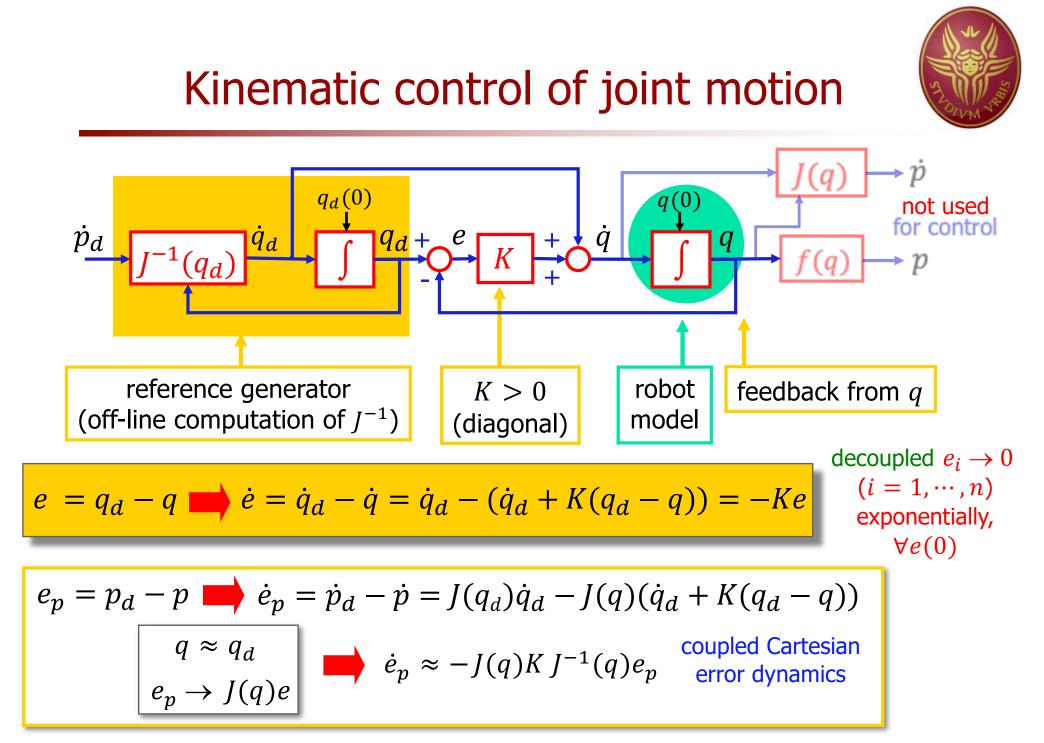

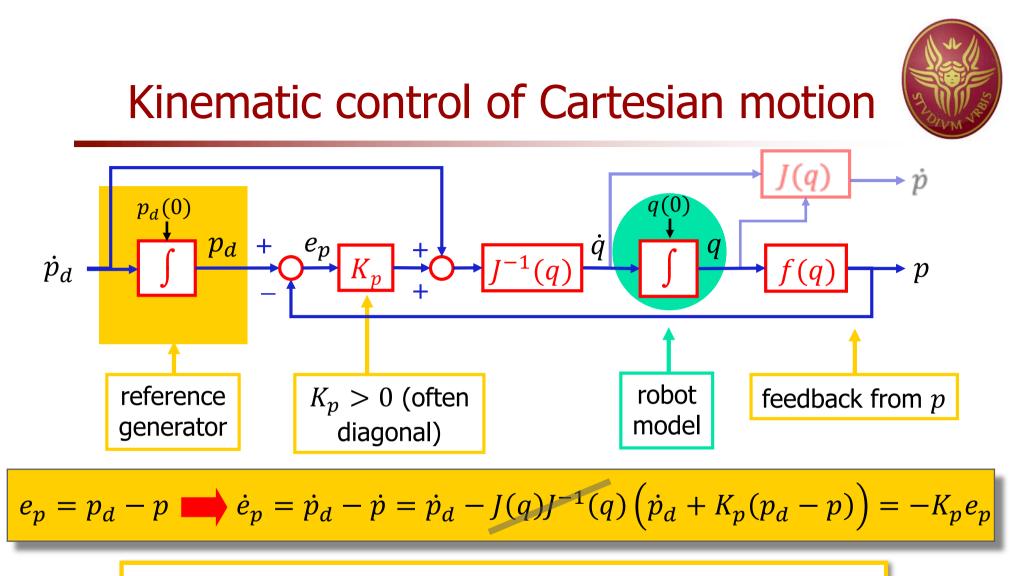

# Control loops in industrial robots

- analog loop of large bandwidth on motor current ( $\propto$  torque)
- analog loop on velocity  $(G_{vel}(s), typically a PI)$
- digital feedback loop on position, with velocity feedforward
- this scheme is local to each joint (decentralized control)

- decoupled  $e_{p,i} \rightarrow 0$  ( $i = 1, \dots, m$ ) exponentially,  $\forall e_p(0)$
- needs on-line computation of the inverse<sup>(\*)</sup> $J^{-1}(q)$
- real-time + singularities issues

 $^{(\ast)}$  or pseudoinverse if m < n

#### Simulation features of kinematic control laws

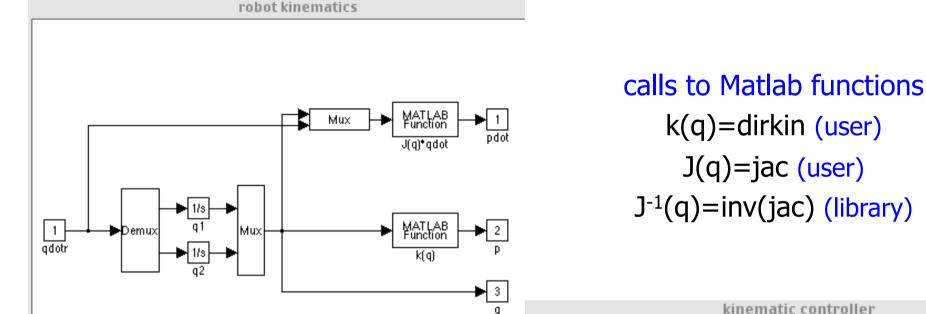

desired reference trajectory: two types of tasks 1. straight line 2. circular path both with constant speed

numerical integration method: fixed step Runge-Kutta at 1 msec

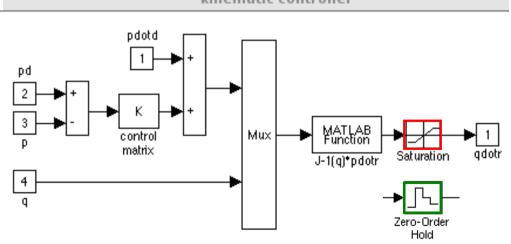

### Simulink blocks

- a saturation (for task 1.) or a sample and hold (for task 2.) added on joint velocity commands
- system initialization of kinematics data, desired trajectory, initial state, and control parameters (in init.m file)

never put "numbers" inside the blocks !

- straight line path with constant velocity
  - $x_d(0) = 0.7 \text{ m}, y_d(0) = 0.3 \text{ m}; v_{d,y} = 0.5 \text{ m/s}, \text{ for } T = 2 \text{ s}$
- Iarge initial error on end-effector position
  - $q(0) = (-45^{\circ}, 90^{\circ}) \Rightarrow e_p(0) = (-0.7, 0.3) \text{ m}$
- Cartesian control gains
  - $K_p = \text{diag}\{20, 20\}$
- (a) without joint velocity command saturation
- (b) with saturation ...

•  $v_{max,1} = 120^{\circ}/\text{s}$ ,  $v_{max,2} = 90^{\circ}/\text{s}$ 

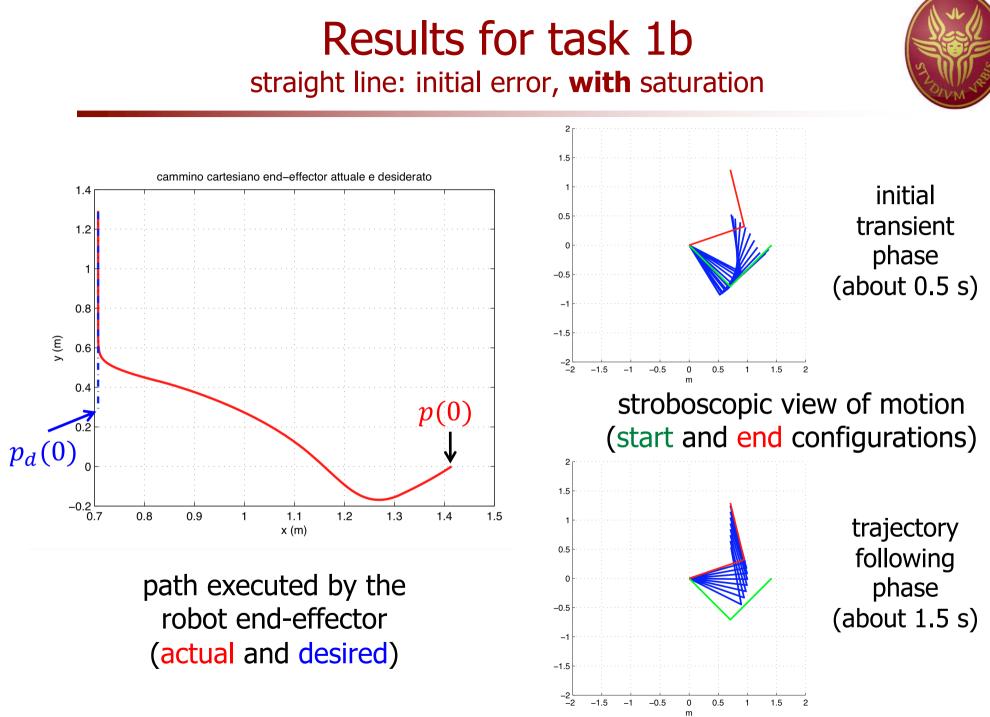

# Results for task 1a (cont) straight line: initial error, **no** saturation

 $p_x$ ,  $p_y$  actual and desired

control inputs  $\dot{q}_{r1}$ ,  $\dot{q}_{r2}$ 

# Results for task 1b (cont) straight line: initial error, with saturation

 $p_x$ ,  $p_y$  actual and desired

control inputs  $\dot{q}_{r1}$ ,  $\dot{q}_{r2}$ (saturated at  $\pm v_{max,1}$ ,  $\pm v_{max,2}$ )

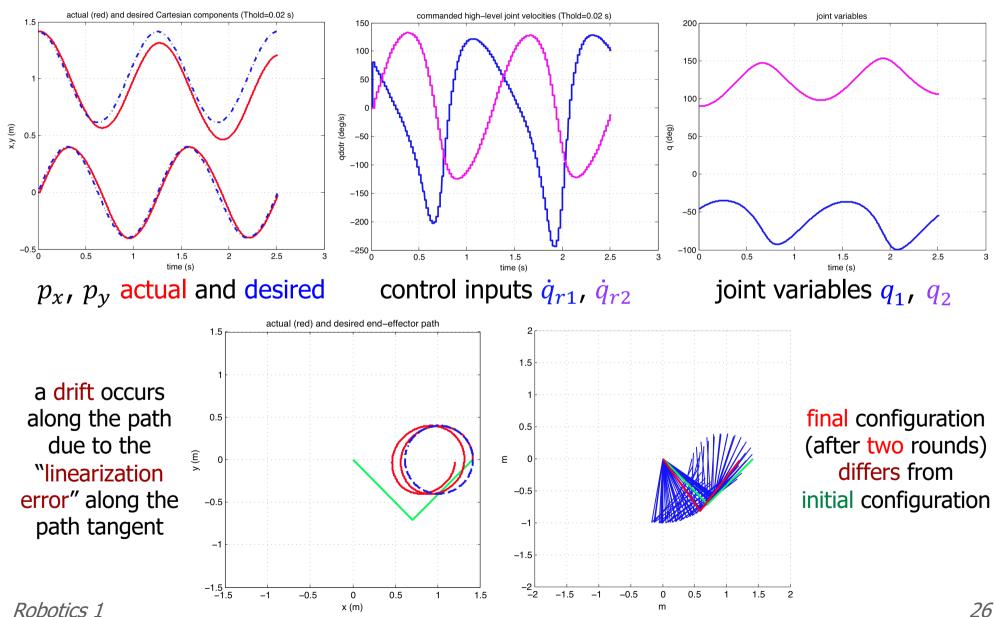

- circular path with constant velocity
  - centered at (1.014, 0) with radius R = 0.4 m;
  - v = 2 m/s, performing two rounds  $\Rightarrow T \approx 2.5$  s
- zero initial error on Cartesian position ("match")
  - $q(0) = (-45^{\circ}, 90^{\circ}) \Rightarrow e_p(0) = 0$
- (a) ideal continuous case (1 kHz), even without feedback
- (b) with sample and hold (ZOH) of  $T_{hold} = 0.02$  s (joint velocity command updated at 50 Hz), but without feedback
- (c) as before, but with Cartesian feedback using the gains
   K<sub>p</sub> = diag{25, 25}

### Results for task 2a circular path: no initial error, continuous control (ideal case)

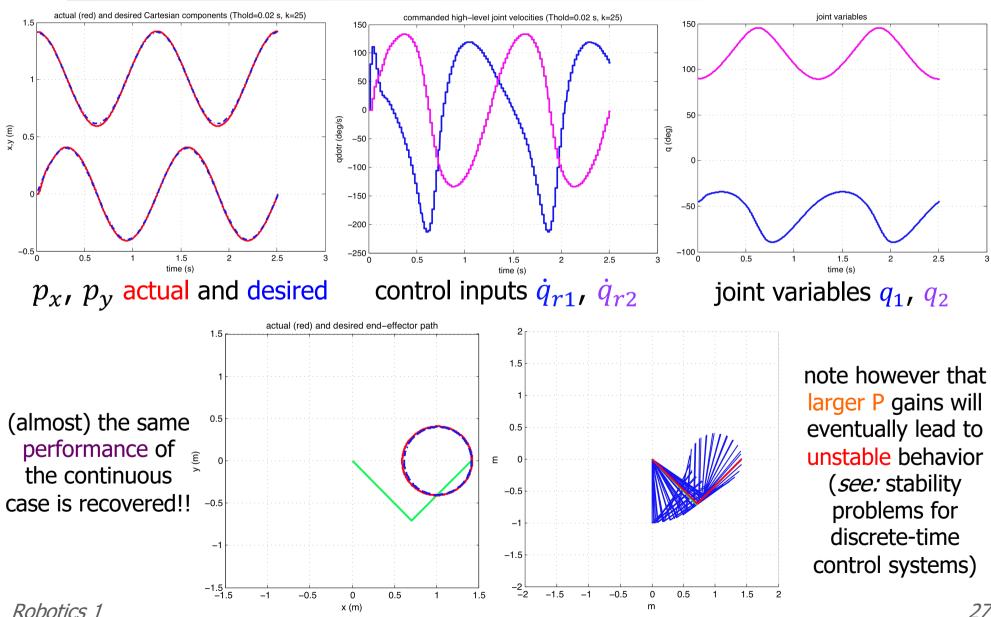

#### Results for task 2b circular path: no initial error, **ZOH** at 50 Hz, **no** feedback

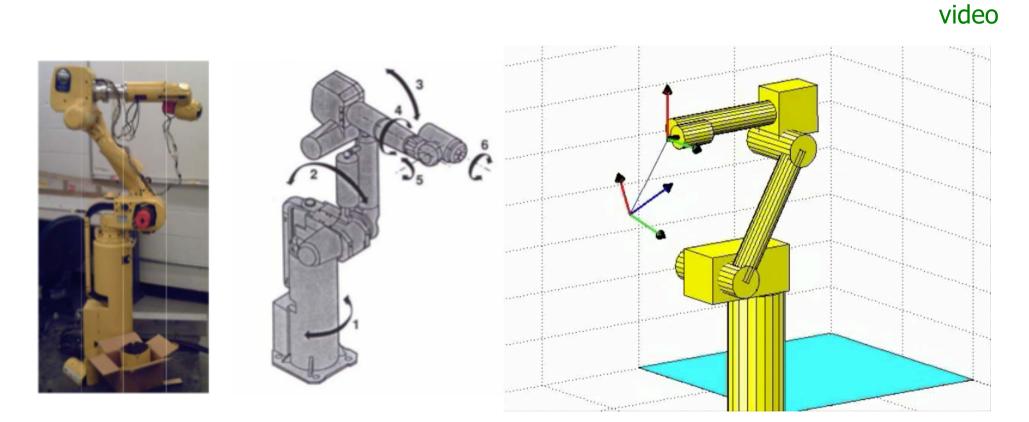

#### Results for task 2c circular path: no initial error, **ZOH** at 50 Hz, with feedback
