Trajectories in Cartesian space

- in general, PTP/MP trajectory planning methods developed in joint space can be applied also in Cartesian/task space
 - consider **independently** each component of the task vector (i.e., a position or an angle of a minimal representation of orientation)
- however, when planning a trajectory for three orientation angles, the resulting global motion cannot be intuitively **visualized** in advance
- moreover, if possible, we still prefer to plan Cartesian trajectories **separately** for **position** and **orientation**
- the number of knots to be interpolated in the Cartesian space may be small (e.g., 2 knots (PTP motion), 3 if a “via point” is added) \Rightarrow use **simple** interpolating paths, such as straight lines, arc of circles, ...

Planning a linear Cartesian motion (in position only)

GIVEN $p_i, p_f \in \mathbb{R}^3$ for the path
and $v_i, v_f \in \mathbb{R}$ (typically = 0) with
bounds $V, A \in \mathbb{R}^+$ for the timing law

$$L = \|p_f - p_i\|$$

path parameterization
 $p(s) = p_i + s(p_f - p_i)$

$\frac{p_f - p_i}{\|p_f - p_i\|} =$ unit vector of directional
cosines of the line

$$s \in [0,1]$$

may also use $s = \sigma/L$, where $\sigma \in [0, L]$ is the
arc length (= length of the path traced so far)

$$\begin{aligned}\dot{p}(s) &= \frac{dp}{ds} \dot{s} = (p_f - p_i) \dot{s} \\ &= \frac{p_f - p_i}{L} \dot{\sigma}\end{aligned}$$

$$\begin{aligned}\ddot{p}(s) &= \cancel{\frac{d^2p}{ds^2}} \dot{s}^2 + \frac{dp}{ds} \ddot{s} = (p_f - p_i) \ddot{s} \\ &= \frac{p_f - p_i}{L} \ddot{\sigma}\end{aligned}$$

...why?

Timing law with trapezoidal speed - 1

given*: L, V, A
find: T_r, T

$$V (T - T_r) = L$$

= area of the
speed profile

$$T_r = \frac{V}{A}$$
$$T = \frac{A L + V^2}{A V}$$

a "coast" phase
exists iff $L > V^2/A$

otherwise ...

triangular speed (bang-bang) profile with

$$\max \dot{\sigma} = \bar{V} = A T_r = A \cdot T/2 \leq V$$

$$\bar{V} \cdot T/2 = L \text{ (= area)}$$

$$T = \sqrt{4L/A}$$

* = other input data combinations are possible (see textbook Sect. 4.4.2, p. 217)

Timing law with trapezoidal speed - 2

$$\sigma(t) = \begin{cases} \frac{At^2}{2} & t \in [0, T_r] \\ Vt - \frac{V^2}{2A} & t \in [T_r, T - T_r] \\ -\frac{A(t-T)^2}{2} + VT - \frac{V^2}{A} & t \in [T - T_r, T] \end{cases} = L$$

used also as timing law in **joint space**!

at each joint j separately, gives fastest motion time (T_j , with V_j and A_j) \Rightarrow **non-coordinated** motion

taking then $T = \max_{j=1, \dots, n} T_j$: the slowest joint imposes the minimum time \Rightarrow **coordinated** motion

it is a **discontinuous** acceleration profile: if required, use for instance a rest-to-rest quintic polynomial timing law

Linear trajectory bounds

from limits in Cartesian space

- for the linear trajectory

$$p(t) = p_i + \sigma(t)K$$

$$\dot{p}(t) = \dot{\sigma}(t) K$$

$$\ddot{p}(t) = \ddot{\sigma}(t) K$$

$$K = \frac{p_f - p_i}{\|p_f - p_i\|} = \frac{p_f - p_i}{L} = \begin{pmatrix} K_x \\ K_y \\ K_z \end{pmatrix}$$

- consider task limits on **velocity norm** and **acceleration norm**

$$\|\dot{p}(t)\| \leq v_{\max}$$

$$\|\ddot{p}(t)\| \leq a_{\max}$$

$$|\dot{\sigma}(t)| \leq v_{\max} = V$$

$$|\ddot{\sigma}(t)| \leq a_{\max} = A$$

- for **componentwise velocity** and **acceleration** task limits

$$\dot{p}_{\{x,y,z\}} \leq v_{\max,\{x,y,z\}}$$

$$\ddot{p}_{\{x,y,z\}} \leq a_{\max,\{x,y,z\}}$$

$$|\dot{\sigma}(t)| \leq \min \left\{ \frac{v_{\max,x}}{K_x}, \frac{v_{\max,y}}{K_y}, \frac{v_{\max,z}}{K_z} \right\} = V$$

$$|\ddot{\sigma}(t)| \leq \min \left\{ \frac{a_{\max,x}}{K_x}, \frac{a_{\max,y}}{K_y}, \frac{a_{\max,z}}{K_z} \right\} = A$$

Concatenation of linear segments

$$\frac{B - A}{\|B - A\|} = K_{AB}$$

$$\frac{C - B}{\|C - B\|} = K_{BC}$$

unit vectors of
directional cosines

given: constant speeds v_1 on linear segment AB

v_2 on linear segment BC

desired transition: blending with constant acceleration for a time ΔT

$$p(t) = \begin{pmatrix} x(t) \\ y(t) \\ z(t) \end{pmatrix} \quad t \in [0, \Delta T] \quad (\text{transition starts at } t = 0)$$

note: during over-fly, the path remains always in the plane specified by the two lines intersecting at B (in essence, it is a planar problem)

Time profiles on components

Timing law during transition

$$\frac{B - A}{\|B - A\|} = K_{AB}$$

$$\frac{C - B}{\|C - B\|} = K_{BC}$$

unit vectors of
directional cosines

$t \in [0, \Delta T]$ (transition **starts** at $t = 0$)

$$\ddot{p}(t) = (v_2 K_{BC} - v_1 K_{AB}) / \Delta T \quad \xrightarrow{\int} \quad \dot{p}(t) = v_1 K_{AB} + (v_2 K_{BC} - v_1 K_{AB}) t / \Delta T$$

$$p(t) = A' + v_1 K_{AB} t + (v_2 K_{BC} - v_1 K_{AB}) t^2 / (2 \Delta T)$$

thus, we obtain a
parabolic blending
(same approach
as in joint space!)

Solution

(various options)

$$B - A' = d_1 K_{AB}$$

$$C' - B = d_2 K_{BC}$$

①

$$p(t) = A' + v_1 K_{AB} t + (v_2 K_{BC} - v_1 K_{AB}) t^2 / (2\Delta T)$$

$$p(\Delta T) = A' + (\Delta T/2)(v_1 K_{AB} + v_2 K_{BC}) = C'$$

$$\longrightarrow -B + A' + (\Delta T/2)(v_1 K_{AB} + v_2 K_{BC}) = C' - B$$

$$\textcircled{1} \longrightarrow d_1 K_{AB} + d_2 K_{BC} = (\Delta T/2)(v_1 K_{AB} + v_2 K_{BC})$$

$$\longrightarrow \boxed{d_1 = v_1 \Delta T / 2} \quad \boxed{d_2 = v_2 \Delta T / 2}$$

by choosing, e.g., d_1
(namely A')

$$\longrightarrow \boxed{\Delta T = 2d_1 / v_1 \longrightarrow d_2 = d_1 v_2 / v_1}$$

A numerical example

- transition: $A = (3,3)$ to $C = (8,9)$ via $B = (1,9)$, with speed from $v_1 = 1$ to $v_2 = 2$
- exploiting **two options** for solution (resulting in **different paths!**)
 - assign transition time: $\Delta T = 4$
 - assign distance from B for departing: $d_1 = 3$ (assigning d_2 for landing handled similarly)

$$\Delta T = 4$$

$$d_1 = 3$$

A numerical example (cont'd)

first option: $\Delta T = 4$ (resulting in $d_1 = 2, d_2 = 4$)

$$\Rightarrow \|\ddot{p}\| = 0.39 \text{ m/s}^2$$

second option: $d_1 = 3$ (resulting in $\Delta T = 6, d_2 = 6$)

$$\Rightarrow \|\ddot{p}\| = 0.17 \text{ m/s}^2$$

actually: similar velocity/acceleration profiles, but with a different time scale!!

Alternative solution (imposing acceleration)

$$\ddot{p}(t) = (v_2 K_{BC} - v_1 K_{AB}) / \Delta T$$

$$v_1 = v_2 = v_{\max} \text{ (for simplicity)}$$

$$\|\ddot{p}(t)\| = a_{\max}$$

$$\begin{aligned} \Delta T &= (v_{\max} / a_{\max}) \|K_{BC} - K_{AB}\| \\ &= (v_{\max} / a_{\max}) \sqrt{2(1 - K_{BC,x}K_{AB,x} - K_{BC,y}K_{AB,y} - K_{BC,z}K_{AB,z})} \end{aligned}$$

$$\text{then, } d_1 = d_2 = v_{\max} \Delta T / 2$$

Application example

plan a Cartesian trajectory from A to C (rest-to-rest)
that avoids the obstacle O , with $a \leq a_{\max}$ and $v \leq v_{\max}$

on $\overline{AA'}$ $\rightarrow a_{\max}$; on $\overline{A'B}$ and $\overline{BC'}$ $\rightarrow v_{\max}$; on $\overline{C'C}$ $\rightarrow -a_{\max}$;
+ over-fly between A'' e C'' (e.g., with a_{\max} in norm)

Other Cartesian paths

- **circular path** through 3 points in 3D (built-in feature) see textbook Ex. 4.3
- linear path for the end-effector with **constant orientation** (available in KRL)
- in robots with **spherical wrist**: planning may be **decomposed** into a path for wrist center and one for E-E orientation, with a common timing law
- though more complex, it may be **convenient** to parameterize the Cartesian geometric path $p(s)$ in terms of its **arc length** (e.g., $\sigma = R\theta$ for circular paths), similarly to what seen in joint space for $q(s)$; the following holds:
 - **velocity** $\dot{p} = dp/dt = (dp/d\sigma)(d\sigma/dt) = p' \dot{\sigma}$
 - $p' =$ unit vector ($\|\cdot\| = 1$) tangent to the path \Rightarrow **tangent** direction $t(\sigma)$
 - $\dot{\sigma} \geq 0$ is the absolute value of the tangential velocity (= **speed**)
 - **acceleration** $\ddot{p} = (dp/d\sigma)(d^2\sigma/dt^2) + (d^2p/d\sigma^2)(d\sigma/dt)^2 = p' \ddot{\sigma} + p'' \dot{\sigma}^2$
 - $\|p''\| =$ **curvature** $\kappa(\sigma)$ ($= 1/\text{radius of curvature}$)
 - $p'' \dot{\sigma}^2 =$ **centripetal** acceleration \Rightarrow **normal** direction $n(\sigma) \perp$ to the path, on the osculating plane; the **binormal** direction is $b(\sigma) = t(\sigma) \times n(\sigma)$
 - $\ddot{\sigma} =$ scalar value (**with any sign**) of the tangential acceleration

Definition of Frenet frame

- for a smooth and non-degenerate curve $p(s) \in \mathbb{R}^3$, parameterized by s (**not** necessarily its arc length), one can define a reference frame as shown

$$p' = dp/ds \quad p'' = d^2p/ds^2$$

derivatives w.r.t. the parameter s

unit tangent vector

$$t(s) = p'(s) / \|p'(s)\|$$

unit normal vector (\in osculating plane)

$$n(s) = t'(s) / \|t'(s)\|$$
$$= p'(s) \times (p''(s) \times p'(s)) / (\|p'(s)\| \cdot \|p''(s) \times p'(s)\|)$$

unit binormal vector

$$b(s) = t(s) \times n(s)$$
$$= p'(s) \times p''(s) / \|p'(s) \times p''(s)\|$$

- general expressions of path **curvature** and **torsion** (at a path point $p(s)$)

$$\kappa(s) = \|p'(s) \times p''(s)\| / \|p'(s)\|^3$$

$$\tau(s) = [p'(s) \cdot (p''(s) \times p'''(s))] / \|p'(s) \times p''(s)\|^2$$

Examples of paths with Frenet frame

Viviani curve

= intersection of a sphere with a tangent cylinder

$$\begin{aligned} x &= r \cos^2 s \\ y &= r \cos s \sin s \\ z &= r \sin s \\ s &\in [-\pi/2, \pi/2] \end{aligned}$$

$$\begin{aligned} x &= r \cos^2 s \\ y &= -r \cos s \sin s \\ z &= -r \sin s \end{aligned}$$

By Ag2gaeh - <https://commons.wikimedia.org/w/index.php?curid=81698760>

By Gonfer <https://commons.wikimedia.org/w/index.php?curid=18558097>

Helix curve (right handed)

$$\begin{aligned} x &= r \cos s \\ y &= r \sin s \\ z &= h s \\ s &\in [0, 2\pi] \end{aligned}$$

$$\begin{aligned} \kappa &= \frac{r}{r^2 + h^2} \\ \tau &= \frac{h}{r^2 + h^2} \end{aligned}$$

By Goldencako - <https://commons.wikimedia.org/w/index.php?curid=7519084>

Exercise

given the path $p(s) = \begin{pmatrix} 6s + 2 \\ 5s^2 \\ -8s \end{pmatrix}, s \in [0, 1]$

- define the Frenet frame $\{t(s), n(s), b(s)\}$
- compute the curvature $\kappa(s)$ and the torsion $\tau(s)$

Optimal trajectories

- for Cartesian robots (e.g., PPP joints)
 1. the straight line joining two position points in the Cartesian space is **one** path that can be executed in **minimum time** under velocity/acceleration constraints (but other such paths exist, if (joint) motion is **not coordinated**)
 2. the optimal timing law is of the bang-coast-bang type in **acceleration** (in this special case, also in terms of motor **torques**)
- for articulated robots (with at least one R joint)
 - 1. e 2. are no longer true in general in the **Cartesian** space, but time-optimality still holds in the **joint** space when assuming **bounds** on **joint velocity/acceleration**
 - straight line paths in the joint space **do not correspond** to straight line paths in the Cartesian space, and vice-versa
 - bounds on joint acceleration are **conservative** (though **kinematically tractable**) w.r.t. actual bounds on motor torques, which involve the full robot **dynamics**
 - when changing robot configuration/state, different torque values are needed to impose the same joint accelerations ...

Planning orientation trajectories

- using minimal representations of orientation (α, β, γ) , e.g., ZXZ **Euler** angles, we can plan a trajectory for each component independently
 - e.g., a linear path in space $\alpha(s), \beta(s), \gamma(s)$, with a cubic timing law $s(t)$
 - ⇒ but **poor prediction/understanding** of the resulting intermediate orientations
- **alternative method** based on the **axis/angle representation**
 - determine (unit) axis ${}^i r$ and angle θ_{if} : $Rot({}^i r, \theta_{if}) = {}^i R_f = R_i^T R_f$ (relative rotation between **initial** and **final** orientation) ⇒ inverse axis-angle problem
 - plan a timing law $\theta(t)$ for the (scalar) angle interpolating $\theta = 0$ with $\theta = \theta_{if}$ in time T (with possible constraints/boundary conditions on its time derivatives)
 - $\forall t \in [0, T], R_i Rot({}^i r, \theta(t))$ specifies the actual end-effector orientation at time t

Orientation trajectory bounds from limits in Cartesian space

- for an orientation path $\phi(s)$ using a minimal representation (e.g., **Euler angles**), consider a limit on the **angular velocity norm**

$$\|\omega(t)\| \leq \omega_{\max}$$

since $\omega(t) = T(\phi(t))\dot{\phi}(t) = T(\phi(s))\phi'(s)\dot{s}(t)$

$$\Rightarrow |\dot{s}(t)| \leq \frac{\omega_{\max}}{\max_{s \in [0,1]} \|T(\phi(s))\phi'(s)\|}$$

- **conservative** handling of limit $\|\dot{\omega}(t)\| \leq \dot{\omega}_{\max}$ as a bound on $|\ddot{s}(t)|$
- with the **axis/angle** representation, it is easy to transfer limits on **angular velocity/acceleration norms** to bounds on timing law $\theta(t)$

$$\begin{array}{lll} \|\omega(t)\| \leq \omega_{\max} & \Rightarrow & \omega(t) = \dot{\theta}(t) r = \theta_{if} \dot{s}(t) r \\ \|\dot{\omega}(t)\| \leq \dot{\omega}_{\max} & \Rightarrow & \dot{\omega}(t) = \ddot{\theta}(t) r = \theta_{if} \ddot{s}(t) r \\ & & (\|r\| = \|R_i^i r\| = \|{}^i r\|) \end{array} \quad \Rightarrow \quad \begin{array}{l} |\dot{s}(t)| \leq \omega_{\max} / \theta_{if} \\ |\ddot{s}(t)| \leq \dot{\omega}_{\max} / \theta_{if} \end{array}$$

A complete position/orientation Cartesian trajectory (simulation)

position $p_i = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \rightarrow p_f = \begin{pmatrix} 3 \\ 4 \\ 5 \end{pmatrix} \quad L = \|p_f - p_i\| = 5.385 \text{ m}$

orientation $R_i = \begin{pmatrix} -1 & 0 & 0 \\ 0 & -\sqrt{2}/2 & -\sqrt{2}/2 \\ 0 & -\sqrt{2}/2 & \sqrt{2}/2 \end{pmatrix} \rightarrow R_f = \begin{pmatrix} -\sqrt{2}/2 & -\sqrt{2}/2 & 0 \\ 0 & 0 & 1 \\ -\sqrt{2}/2 & \sqrt{2}/2 & 0 \end{pmatrix}$

${}^iR_f = R_i^T R_f = \begin{pmatrix} \sqrt{2}/2 & \sqrt{2}/2 & 0 \\ 1/2 & -1/2 & -\sqrt{2}/2 \\ -1/2 & 1/2 & -\sqrt{2}/2 \end{pmatrix}$

using **ZYZ Euler** angles [rad]

absolute $\phi_i = \begin{pmatrix} -\pi/2 \\ \pi/4 \\ -\pi/2 \end{pmatrix} \rightarrow \phi_f = \begin{pmatrix} \pi/2 \\ \pi/2 \\ \pi/4 \end{pmatrix}$ **relative** $\phi_{if} = \begin{pmatrix} -\pi/2 \\ 3\pi/4 \\ \pi/4 \end{pmatrix}$

using **axis/angle** representation (from iR_f) ${}^i r = \begin{pmatrix} 0.912 \\ 0.378 \\ -0.156 \end{pmatrix} \quad \theta_{if} = 2.419 \text{ rad}$

linear parametrized paths

$$p(s) = p_i + s(p_f - p_i) \quad \left\{ \begin{array}{l} \phi(s) = \phi_i + s(\phi_f - \phi_i) \\ {}^i\phi(s) = s\phi_{if} \\ \theta(s) = s\theta_{if} \end{array} \right. \quad s \in [0,1]$$

Uniform time scaling

- for a given path $p(s)$ (in joint or Cartesian space) and timing law $s(\tau)$ ($\tau = t/T$, T ="motion time"), we need to **check if existing bounds** v_{\max} on (joint) velocity and/or a_{\max} on (joint) acceleration **are violated or not**
 - ... unless such constraints have already been taken into account during the trajectory planning, e.g., by using a bang-coast-bang acceleration timing law
- **velocity scales linearly** with motion time
 - $\dot{p} = dp/dt = (dp/ds)(ds/d\tau) \cdot 1/T$
- **acceleration scales quadratically** with motion time
 - $\ddot{p} = d^2p/dt^2 = ((d^2p/ds^2)(ds/d\tau)^2 + (dp/ds)(d^2s/d\tau^2)) \cdot 1/T^2$
- if motion is unfeasible, **increase** time $T \rightarrow T_s = kT$ ($k > 1$), based on the "most violated" constraint (max of the ratios $|v|/v_{\max}$ and $|a|/a_{\max}$)
- if motion is "too slow" for the robot capabilities, **decrease** $T \rightarrow T_s$ ($k < 1$)
 - in both cases, after **scaling**, there will be (at least) one instant of saturation (for at least one variable)
 - **no need** to re-compute motion profiles from scratch!

Numerical example - 1

- 2R planar robot with links of unitary length (1 [m])
- linear Cartesian path $p(s)$: $q_i = (110^\circ, 140^\circ) \Rightarrow p_i = f(q_i) = (-0.684, 0) \Rightarrow p_f = (0.816, 1.4)$ [m], with rest-to-rest cubic timing law $\sigma(t)$, $T = 1$ s
- joint space bounds: max (absolute) velocity $v_{\max,1} = 2$, $v_{\max,2} = 2.5$ [rad/s], max (absolute) acceleration $a_{\max,1} = 5$, $a_{\max,2} = 7$ [rad/s²]

path length $L = 2.0518$ [m]

$T = 1$

arc length

$$p(\sigma) = p_i + \frac{p_f - p_i}{L} \sigma, \quad \sigma \in [0, L]$$

Numerical example - 2

- **violation** of both joint velocity and acceleration bounds with $T = 1$ s
 - max relative violation of joint **velocities**: $k_{\text{vel}} = 2.898 = \max \{1, |\dot{q}_1|/v_{\text{max},1}, |\dot{q}_2|/v_{\text{max},2}\}$
 - and of joint **accelerations**: $k_{\text{acc}} = 6.2567 = \max \{1, |\ddot{q}_1|/a_{\text{max},1}, |\ddot{q}_2|/a_{\text{max},2}\}$
- minimum **uniform time scaling** of Cartesian trajectory to **recover feasibility**

$$k = \max \{1, k_{\text{vel}}, \sqrt{k_{\text{acc}}}\} = \max \{1, 2.898, 2.5023\} = 2.898 \Rightarrow T_s = kT = 2.898 > T$$

— = joint 1 — = joint 2

Numerical example - 3

- **scaled** trajectory with $T_s = 2.898$ s
 - speed [acceleration] on path and joint velocities [accelerations] scale linearly [quadratically]
